# 🔹 String Constructor in C++ (`std::string`) – Complete & Clear

A **constructor** is used to **create and initialize** a string object in different ways.

Header:

```
#include <string>
```

---

## 1️⃣ Default Constructor

➡️ Creates an **empty string**

```
string s;
cout << s;        // empty
cout << s.size(); // 0
```

---

## 2️⃣ Constructor with C-String

➡️ Initialize with **character array / string literal**

```
string s("Hello");
string s2 = "World";
```

---

## 3️⃣ Copy Constructor

➡️ Create a new string by **copying another string**

```
string s1 = "C++";
string s2(s1);
```

---

## 4️⃣ Substring Constructor

➡️ Create string from **part of another string**

```
string s("Programming", 0, 4);
cout << s;   // Prog
```

**Syntax**

```
string(str, start_index, length);
```

---

## 5️⃣ Fill Constructor

➡️ Create string with **repeated characters**

```
string s(5, 'A');
cout << s;   // AAAAA
```

---

## 6️⃣ Iterator Constructor

➡️ Create string using **iterators**

```
string s1 = "Hello World";
string s2(s1.begin(), s1.begin() + 5);

cout << s2;  // Hello
```

---

## 7️⃣ Move Constructor (C++11)

➡️ Transfers resources (faster, no copy)

```
string s1 = "Hello";
string s2 = move(s1);

cout << s2;  // Hello
```

📌 `s1` becomes empty or unspecified state

---

## 8️⃣ Constructor from `std::string_view` (C++17)

➡️ Lightweight string creation

```
string_view sv = "C++";
string s(sv);
```

---

## 🔹 Summary Table

| Constructor Type | Example |
|---|---|
| Default | `string s;` |
| C-string | `string s("Hi");` |
| Copy | `string s2(s1);` |
| Substring | `string s("Hello",1,3);` |
| Fill | `string s(4,'x');` |
| Iterator | `string(s.begin(), s.end())` |
| Move | `string s2(move(s1));` |

---

## ⚠️ Common Mistakes

❌ `string s(10);` → ERROR (no char specified)
❌ Confusing substring constructor order
❌ Forgetting `#include <string>`

---

## ✅ Best Practice

✔ Use constructor that fits your use case
✔ Prefer **copy or move** over manual assignment
✔ Use **iterator constructor** for slicing strings

---

## 🔚 Final Note

String constructors give you **full control** over how a string is created.

If you want next:

- **String methods practice**
- **MCQ for exams**
- **Interview questions**
- **Real-world examples**

Just say 👍

## 🔹 Sorting a String in C++ (using `sort()`)

In C++, **strings can be sorted directly** using the built-in `sort()` function from the STL.

---

## 1️⃣ Header Required

```
#include <algorithm>
#include <string>
```

---

## 2️⃣ Basic String Sort (Ascending Order)

```
string s = "dcab";
sort(s.begin(), s.end());
cout << s;
```

**Output**

```
abcd
```

📌 Sorts characters based on **ASCII values**

---

## 3️⃣ Sort String in Descending Order

```
string s = "dcab";
sort(s.begin(), s.end(), greater<char>());
cout << s;
```

**Output**

```
dcba
```

## 4️⃣ Sort Substring (Partial Sort)

```
string s = "programming";
sort(s.begin(), s.begin() + 4);
cout << s;
```

**Output**

```
porgramming
```

(Only first 4 characters sorted)

---

## 5️⃣ Sort String with Uppercase & Lowercase

```
string s = "aBcD";
sort(s.begin(), s.end());
cout << s;
```

**ASCII order**

```
BDac
```

📌 Uppercase letters come before lowercase.

---

## 6️⃣ Case-Insensitive Sort (Custom Comparator)

```
bool cmp(char a, char b){
    return tolower(a) < tolower(b);
}

int main(){
    string s = "aBcD";
    sort(s.begin(), s.end(), cmp);
    cout << s;
}
```

**Output**

```
aBcD
```

---

## 7️⃣ Sort Each Word Separately

```
string s = "cat bat apple";
stringstream ss(s);

string word, result = "";
while(ss >> word){
    sort(word.begin(), word.end());
    result += word + " ";
}

cout << result;
```

**Output**

```
act abt aelpp
```

---

## 8️⃣ Sort String Using Frequency (Advanced)

```
string s = "banana";
map<char,int> freq;

for(char c : s)
    freq[c]++;

for(auto p : freq)
    cout << string(p.second, p.first);
```

**Output**

```
aaabnn
```

---

## 9️⃣ Important Notes

✔ Time complexity: **O(n log n)**
✔ `sort()` works on **iterators**

✔ Sorting modifies the original string

---

## 🔚 Summary

- Use `sort(s.begin(), s.end())`
- ASCII based sorting by default
- Custom comparator for special needs

---

If you want:
✅ **String sorting problems**
✅ **Interview questions**
✅ **MCQ**
✅ **Real contest problems**

Just tell me 😊

---

## 🔹 Range-Based `for` Loop in C++ (Easy & Complete)

The **range-based for loop** is a **simpler and safer way** to loop through containers like **string, array, vector, map, set**, etc.

---

## 1️⃣ Syntax

```
for (data_type variable : container) {
    // use variable
}
```

---

## 2️⃣ Range-Based Loop with `string`

```
string s = "Hello";

for(char c : s){
    cout << c << " ";
}
```

**Output**

```
H e l l o
```

📌 Iterates **character by character**

---

## 3️⃣ Modify String Characters (Use Reference 🔥)

```
string s = "hello";

for(char &c : s){
    c = toupper(c);
}

cout << s;   // HELLO
```

✔ `&` allows modification
❌ Without `&`, original string won't change

---

## 4️⃣ Read-Only Loop (Best Practice)

```
for(const char &c : s){
    cout << c;
}
```

✔ Prevents accidental modification
✔ Faster & safer

---

## 5️⃣ Range-Based Loop with Array

```
int a[] = {1,2,3,4};

for(int x : a){
    cout << x << " ";
}
```

---

## 6️⃣ Range-Based Loop with `vector`

```
vector<int> v = {10,20,30};

for(int x : v){
    cout << x << " ";
}
```

---

## 7️⃣ Range-Based Loop with `map`

```
map<int,string> m = {{1,"A"}, {2,"B"}};

for(auto p : m){
    cout << p.first << " " << p.second << endl;
}
```

---

## 8️⃣ Using `auto` Keyword (Recommended)

```
for(auto c : s){
    cout << c;
}
```

---

## 9️⃣ Compare with Normal `for` Loop

| Normal `for` | Range-based `for` |
|---|---|
| Index needed | No index |
| More code | Less code |
| Error-prone | Safer |
| Old style | Modern C++ |

---

## 🔟 When NOT to Use

❌ When index is needed
❌ When iterating partially
❌ When skipping elements

## 🧠 Best Practices

✔ Use `const auto&` for read-only
✔ Use `auto&` to modify
✔ Prefer range-based loop for clarity

---

## 🔚 Summary

- Introduced in **C++11**
- Cleaner & safer iteration
- Works with all STL containers & strings

---

If you want:
✅ **MCQ**
✅ **Practice problems**
✅ **Comparison with iterators**
✅ **Interview questions**

Just say 👍

## 🔹 `reverse()` Function in C++ (String Reverse)

In C++, the `reverse()` function is used to **reverse the order of elements** in a container like **string, array, vector**, etc.

---

## 1️⃣ Header Required

```
#include <algorithm>
```

---

## 2️⃣ Syntax

```
reverse(start_iterator, end_iterator);
```

For string:

```
reverse(s.begin(), s.end());
```

---

## 3️⃣ Reverse a String (Basic)

```
string s = "Hello";
reverse(s.begin(), s.end());
cout << s;
```

**Output**

```
olleH
```

📌 The original string is **modified**

---

## 4️⃣ Reverse Part of a String (Substring)

```
string s = "programming";
reverse(s.begin(), s.begin() + 4);
cout << s;
```

**Output**

```
gorpamming
```

(Only first 4 characters reversed)

---

## 5️⃣ Reverse Using Range-Based for Loop (Display Only)

```
string s = "C++";

reverse(s.begin(), s.end());

for(char c : s){
    cout << c;
}
```

---

## 6️⃣ Reverse Using Iterators (Manual – Not Recommended)

```
string s = "Hello";

for(auto it = s.rbegin(); it != s.rend(); it++){
    cout << *it;
}
```

📌 `rbegin()` → last character
📌 `rend()` → before first character

(This prints reversed string without modifying original)

---

## 7️⃣ Reverse Words in a String (Advanced)

```
string s = "I love C++";
stringstream ss(s);

string word, result = "";
while(ss >> word){
    reverse(word.begin(), word.end());
    result += word + " ";
}

cout << result;
```

**Output**

```
I evol ++C
```

---

## 8️⃣ Reverse String Using `swap()` (Logic-Based)

```
string s = "abcd";
int i = 0, j = s.size() - 1;

while(i < j){
    swap(s[i], s[j]);
    i++; j--;
}

cout << s;
```

---

## 9️⃣ Time Complexity

⏱️ **O(n)** — very efficient

---

## 🔚 Summary

✔ `reverse()` is part of `<algorithm>`
✔ Works on iterators
✔ Modifies original container
✔ Best way to reverse a string in C++

---

## ✅ Best Practice

Use:

```
reverse(s.begin(), s.end());
```

---

If you want next:

- **Palindrome check**
- **Reverse sentence word-wise**
- **Interview questions**
- **MCQ**

Just tell me 👍

## ✅ Codeforces "Reverse Word" Solution

👉 This usually refers to **Codeforces 41A – Translation**

---

## 🔹 Problem Summary (41A – Translation)

- You are given **two strings**
  - `s` (original word)
  - `t` (translated word)
- **Task:**

Reverse `s` and check if it is **equal to** `t`

---

## 🔹 Approach

1. Read string `s` and `t`
2. Reverse `s` using `reverse()`
3. Compare reversed `s` with `t`
4. Print:
   - `"YES"` if equal
   - `"NO"` otherwise

---

## 🔹 C++ Solution (Accepted)

```cpp
#include <bits/stdc++.h>
using namespace std;

int main() {
    string s, t;
    cin >> s >> t;

    reverse(s.begin(), s.end());

    if (s == t)
        cout << "YES";
    else
        cout << "NO";

    return 0;
}
```

---

## 🔹 Example

**Input**

```
code
edoc
```

**Output**

```
YES
```

---

## 🔹 Key Points

- `reverse()` is from `<algorithm>`
- String comparison using `==`
- Time Complexity: **O(n)**

---

If you want:
✅ **Alternative solution without `reverse()`**
✅ **Other Codeforces string problems**
✅ **MCQ / interview explanation**

Just tell me 👍

---

## 🔹 Functions Inside a Class in C++ (Member Functions)

In C++, **functions inside a class** are called **member functions**. They **define behavior** for the objects of that class.

---

## 1️⃣ Basic Syntax

```cpp
#include <iostream>
using namespace std;

class Student {
public:
    string name;
    int roll;

    // Member function
    void display() {
        cout << "Name: " << name << ", Roll: " << roll << endl;
    }
};

int main() {
    Student s1;
```

```
    s1.name = "AtiAr";
    s1.roll = 12;

    s1.display();  // Call the member function
}
```

**Output:**

```
Name: AtiAr, Roll: 12
```

---

## 2️⃣ Types of Member Functions

| Type | Description | Example |
|---|---|---|
| **Normal function** | Regular function inside class | `void display()` |
| **Inline function** | Defined inside class | Automatically inline |
| **Const function** | Does **not modify** object | `void show() const {}` |
| **Static function** | Belongs to class, not object | `static void greet() {}` |
| **Friend function** | Access private members | `friend void fun(Student s);` |

---

## 3️⃣ Function Outside Class

You can **declare inside class** and **define outside**:

```
class Student {
public:
    string name;
    int roll;
    void display();  // Declaration
};

// Definition outside class
void Student::display() {
    cout << "Name: " << name << ", Roll: " << roll << endl;
}
```

---

## 4️⃣ Function Returning Values

```
class Student {
public:
    int roll;
    int getRoll() {
        return roll;
    }
};

int main() {
    Student s;
    s.roll = 25;
    cout << s.getRoll();
}
```

**Output:**

```
25
```

---

## 5️⃣ Function with Parameters

```
class Student {
public:
    void setData(string n, int r) {
        name = n;
        roll = r;
    }
    void display() {
        cout << name << " " << roll << endl;
    }
private:
    string name;
    int roll;
};

int main() {
    Student s;
    s.setData("AtiAr", 12);
    s.display();
}
```

**Output:**

```
AtiAr 12
```

## 6️⃣ `this` Pointer Inside Member Function

- `this` is a **pointer to current object**
- Useful when **parameter name = member name**

```
class Student {
public:
    string name;
    void setName(string name) {
        this->name = name; // differentiate member & parameter
    }
};
```

---

## 7️⃣ Inline Member Function

- **Small functions** can be **defined inside class**
- Compiler may optimize them

```
class Student {
public:
    void greet() { cout << "Hello\n"; }
};
```

---

## 8️⃣ Const Member Function

- Guarantees **doesn't modify object**

```
class Student {
public:
    string name;
    void show() const {
        cout << name << endl;
    }
};
```

---

## ✅ Key Points

- Functions inside class = **member functions**

- Can **access members directly**
- Can be **defined inside or outside**
- `this` pointer points to the current object
- Can return values, take parameters, or be `static` / `const`

---

If you want, I can make a **full example combining:**

- Function inside class
- Parameters & return values
- `this` pointer usage
- Static & const functions

So you have **one complete reference example** for learning and interview.

Do you want me to do that?

## 🔹 Copying Dynamic Objects in C++ (Deep Copy vs Shallow Copy)

When you **create objects dynamically** (using `new`), copying them **requires care** to avoid memory issues.

---

## 1️⃣ Problem with Default Copy (Shallow Copy)

```
#include <iostream>
using namespace std;

class Student {
public:
    string* name;

    Student(string n) {
        name = new string(n);
    }

    ~Student() {
        delete name;
    }
};

int main() {
    Student s1("AtiAr");
    Student s2 = s1; // Default copy (shallow)
```

```
    cout << *s1.name << " " << *s2.name << endl;
}
```

**Problem:**

- Both `s1` and `s2` point to **same memory**
- `delete` in destructor runs **twice** → **crash**

---

## 2️⃣ Deep Copy (Correct Way)

- Allocate **new memory** for copy
- Copy the **value**, not the pointer

```
#include <iostream>
using namespace std;

class Student {
public:
    string* name;

    // Constructor
    Student(string n) {
        name = new string(n);
    }

    // Copy Constructor (Deep Copy)
    Student(const Student &s) {
        name = new string(*s.name); // allocate new memory
    }

    // Destructor
    ~Student() {
        delete name;
    }

    void display() {
        cout << *name << endl;
    }
};

int main() {
    Student s1("AtiAr");
    Student s2 = s1;  // Deep copy

    s1.display();
```

```
    s2.display();

    *s1.name = "Rahman"; // Modify s1
    s1.display();
    s2.display();       // s2 unaffected
}
```

**Output:**

```
AtiAr
AtiAr
Rahman
AtiAr
```

✅ Safe deep copy: **changes to one object don't affect the other**

---

## 3️⃣ Key Notes

| Concept | Shallow Copy | Deep Copy |
|---|---|---|
| Memory | Shares pointer | New memory allocated |
| Destructor | Risk of double delete | Safe |
| Value change | Affects both | Independent |

---

## 4️⃣ Dynamic Object Creation

```
Student* s3 = new Student("Dynamic");
Student* s4 = new Student(*s3); // Deep copy

s3->display();
s4->display();

delete s3;
delete s4;
```

---

## 5️⃣ Summary

1. **Dynamic objects** need **custom copy constructor** for safety

2. **Always free memory** in destructor
3. Deep copy prevents **crashes and data corruption**

---

If you want, I can make a **full C++ class example** showing:

- Dynamic memory
- Copy constructor
- Assignment operator overload
- Destructor

So it becomes a **perfect reference for dynamic object handling**.

Do you want me to do that?

## 🔹 Segmentation Fault in C++ (When & Why It Happens)

A **Segmentation Fault (Segfault)** occurs when a program tries to **access memory it shouldn't**.

It's a runtime error, not a compile-time error.

---

## 1️⃣ Common Causes

### 1. Accessing Null or Uninitialized Pointer

```
int* p = nullptr;
*p = 10; // ❌ Segmentation fault
```

---

### 2. Accessing Memory Out of Bounds

```
int arr[5] = {1,2,3,4,5};
cout << arr[10]; // ❌ Out-of-bounds → segfault possible
```

For strings:

```
string s = "abc";
cout << s[5]; // ❌ Invalid index → may cause segfault
```

---

## 3. Using Dangling Pointer

```
int* p = new int(10);
delete p;
*p = 20; // ❌ Accessing deleted memory → segfault
```

---

## 4. Double Free / Delete

```
int* p = new int;
delete p;
delete p; // ❌ Segfault
```

---

## 5. Stack Overflow (Too Much Recursion)

```
void func() {
    func(); // ❌ infinite recursion → segfault
}
```

---

## 6. Improper Dynamic Memory Handling in Classes

```
class Student {
public:
    string* name;
    Student(string n) { name = new string(n); }
    ~Student() { delete name; }
};

int main() {
    Student s1("AtiAr");
    Student s2 = s1; // ❌ shallow copy → double delete → segfault
}
```

---

## 7. Using Freed or Deleted Objects

```
Student* s = new Student("A");
delete s;
```

```
s->display(); // ❌ Accessing freed memory → segfault
```

---

## 2️⃣ How to Avoid Segmentation Fault

1. Initialize pointers before use
2. Always check **bounds of arrays / strings**
3. Avoid dangling pointers
4. Use **deep copy** for dynamic objects
5. Don't delete memory twice
6. Prefer **smart pointers** (`unique_ptr`, `shared_ptr`)
7. Be careful with recursion

---

## ✅ Quick Debug Tips

- Compile with `-g` flag and use **gdb**
- Print pointer addresses before access
- Check array and string indices
- Tools: `valgrind` can detect memory errors

---

Segmentation fault occurs **any time the program accesses invalid memory**, e.g.:

- `nullptr`
- Deleted object
- Out-of-bounds array / string
- Shallow copy of dynamic memory

---

If you want, I can make a **small C++ example showing all segfault causes**, so you can **see each case clearly**.

Do you want me to do that?

---
